ESSENTIAL PATIENT INFORMATION

- Payment is required on the day of treatment. We accept credit cards (Visa, Mastercard, EFTPOS). NO CASH during COVID 19 restrictions.
- Complimentary Wi-Fi is provided for your convenience
- Bring a jacket or a scarf in case you get cold during the infusion
- Please note there is no facility provided for the care of children
- For **patient privacy**, we ask that any person accompanying you remains in the waiting room
- Please wear loose fitting clothing to your appointment so your sleeve can be pushed well above the elbow to allow insertion of the intravenous (IV) cannula, and so you are comfortable sitting for the required time
- · Please ensure you have eaten and are adequately hydrated prior to your appointment.

Doing this makes the IV cannulation easier and more comfortable

If you suffer from a heart or kidney condition, please ask your doctor the appropriate amount of hydration (fluid intake) you should have prior to the infusion

INTRAVENOUS (IV) INFUSIONS

For the purpose of administering intravenous (IV) fluids, or medications, directly into the blood circulation, an IV cannula is inserted into a vein. At The Infusion Clinic, the IV cannula will be inserted by a trained nurse.

To ensure a safe infusion a large vein is selected, usually in the forearm. A tourniquet is applied, then a small plastic tube (cannula) is inserted into the vein via a needle. Once the cannula is inserted the needle is removed, leaving the soft cannula in the vein for administration of the medication and/or IV fluid. The tourniquet is removed, and a dressing applied to secure the cannula.

Discomfort should be minimal and disappears soon after the needle is removed from the cannula.

The medication and/or IV fluid is then attached to the cannula for administration into the vein.

Following completion of the infusion the cannula is removed and pressure is applied to the site to stop any bleeding.

Bruising and irritation may occur at the cannula site for several days following the infusion. There is a small risk of infection with any medical procedure, please monitor the IV site over the next 7 days for redness or pain. Should either occur you should see your doctor for further assessment and any required treatment.

IRON INFUSIONS

Iron is an essential mineral within your body. Adequate levels are required for the normal function of muscles (including the heart) and the normal production of haemoglobin and red blood cells, which carry oxygen in the blood around your body. Iron deficiency can cause lethargy, fatigue and lack of concentration, and in more severe cases, can cause anaemia (low blood levels). This can cause a pale complexion, dizziness, shortness of breath, and a reduced capacity for activity. In pregnancy, iron deficiency can cause restricted foetal growth leading to an underweight baby. Iron deficiency has many causes which may require further investigation by your doctor.

Replacing iron by an IV infusion allows for rapid restoration of the body's healthy iron levels with few side-effects, unlike oral tablets which take a number of months to have an effect and can cause gastro-intestinal effects including constipation and stomach upsets.

You have been referred for an iron infusion for treatment of iron deficiency. This is where an iron-containing medication is administered into a vein via an infusion and cannula, and into your bloodstream.

In extremely rare cases, where the IV cannula is dislodged, the skin surrounding the injection site may become permanently discoloured (tattooed). The risk of this occurring is less than one in 1000.

Intravenous iron, for example Ferinject or Monofer, are medications used to treat iron deficiency. These medications are administered over 15-30 minutes, with additional IV hydration administered following for a further 30 minutes to help minimise any potential side-effects. Specific dosages may require you to have two infusions to safely administer the medication, but this will be discussed with you when you book

vour appointment. If you are pregnant, intravenous iron is safe to administer after the 16th week of pregnancy. However, if you are pregnant, you should talk with your doctor about the benefits and risks of iron infusion during pregnancy.

In general, side-effects with iron infusion are uncommon. Side-effects may include flu-like symptoms, nausea, dizziness, headaches, low phosphate levels and muscle/joint aches or pains.

If you have any questions regarding your iron infusion, feel free to browse the FAQ section of The Infusion Clinic website or submit a query online.d any required treatment.
